

PRODUCT ATTRACTOR ROADMAP

THE PROBLEM

Modern internet content is huge and full of AI content. Users find it hard to search for creators or people who match one personal visual taste. Text search is not enough because people often can not explain why they like one specific person or vibe. This problem makes people lose time when they search for movies with actors in their taste on Netflix, bloggers on YouTube, or maybe unknown singers to watch. This also happens in dating apps or social networks where visual appeal and charisma act as one factor of interest.

MY SOLUTION

Project Attractor will help to find persons in your taste on this internet and in real life. It will scan photos from one folder, build one micro-model of user tastes, and help to search for web content and persons on smartphone photos with high probability to match user taste.

TECHNICAL APPROACH

I will train one model using some photos in one user folder. This model will understand user tastes even if this user does not understand them. I plan to use up to 4 levels of analysis: face and small accessories, body shape, clothes and big accessories, and environment (objects in hands, movement direction, interior style). I will test different technical tools (like Ultralytics framework YOLO, maybe SAM 2) for every level to see what gives better results to detect objects with this needed charisma. In this end, I want face detection to work as one minimum goal. I want to identify all persons in user taste even on one smartphone photo of some crowd. I saw how bad crowd recognition works in my laboratory work, but I will try to fix this thing. As one bonus, I might build prompt generation for manual web search.

DATA PLAN

Parameter	Project Plan
Data Source	One custom dataset from saved photos
Volume	50 images
Labels	Person, Face
Tools	YOLO and SAM 2

SUCCESS METRICS

My primary metric is face detection accuracy (without clothes, body, accessories, or environment for now). I want to reach 85 percent correct matches. Then I can develop this project into one commercial product. I will add those three other detection levels. This will be very subjective because matching my taste is one subjective metric. My secondary metric is inference speed. This model must process one crowd photo in under 2 seconds on my PC, or maximum on my smartphone. I will also need to learn deep about object detection and model training for my own objects.

MILESTONE PLAN (ROADMAP)

RISKS AND RESOURCES

Risk 1

Crowd complexity

Plan B for Risk 1

I will check maximum number of people this model can detect

Risk 2

I do not fully understand tools to train this model for specific face details

Plan B for Risk 2

I will watch internet videos and test different Python libraries one by one

Risk 3

I do not fully understand what technologies and settings to use for every charisma level

Plan B for Risk 3

I will watch internet videos and test different Python libraries one by one

Resources

I will use Google Colab with free T4 GPU if I can not configure my PC. I tried to prepare it for laboratory work and saw I need to download many libraries, and they do not work out of this box like in Google Colab. Estimated cost is 0 dollars

THANK YOU

I'll do my best within the limits of my AI knowledge
